Kenneth D. Sibley

This invention relates to tyre deflation detectors.

Background of the invention

When tyres on vehicles and in particular on loaded trucks are under inflated or flat this causes serious problems. In particular riding on a loaded truck on under-inflated or flat tyres causes a massive heat build-up and distortion of the profile of the tyres which destroys under-inflated or flat tyres completely, i.e. not just the tread but the side-walls and the carcass.

When a "flat" occurs on a side-by-side configuration, the good tyre then bears the load of both the tyres causing excessive wear on the good tyre. If this condition persists the two tyres bulge and rub against each other causing a tremendous heat build-up in both tyres and the resultant destruction of both tyres. This is a costly event as of course is the down time of the vehicle. Furthermore there is the serious problem of large chunks of tyre (often the tread of retreaded tyres) falling off, being either thrown by the tyre into the path of on-coming traffic or just lying in the path of traffic threatening damage to vehicles on the road. Such thrown off tyre chunks may also snag and damage the brake lines resulting in brake failure.

It will be appreciated that tyres, and in particular tyres used trucks and lorries, are extremely expensive items so that the destruction of a tyre has serious economic consequences. In addition if one or
5 more tyres are deflated this will cause increase drag on the lorry which will result in increased fuel consumption and consequent cost in the running of the truck or lorry.

A major problem with multi-wheel vehicles is
10 that where there is a flat on under-inflation of one or more tyres, by the time the driver is aware of this problem it is usually too late.

Numerous deflation detectors have been proposed
15 to provide the driver of a vehicle of warnings that one or more tyres are under-inflated. The bulk of these devices include detectors incorporated into the tyre inflation valves with batteries that provide a signal when the pressure falls. Typical of such
20 devices are those which are described and illustrated in GB 2 267 179-A, GB 1 294 967 and EP-0 351 997-A2.

While these devices may be satisfactory in operation when initially set up, they suffer from the problem that the driver will normally be unaware
25 of when the batteries run down and consequently that the devices are inoperative.

Brief Summary of the Invention

*Revised
7/4/88*

According to one aspect of the present invention there is provided a tyre condition indicating device comprising a detector for detecting the condition of a tyre on a wheel or a wheel of a vehicle rotatable about a wheel axis, preferably for detecting pressure
5 of the tyre, a signal emitter emitting a signal when the detector detects the said condition and power supply means providing power to the signal emitter to emit the signal as aforesaid, wherein the power
10 supply means comprises an electric power generator comprising first and second parts that are relatively rotatable about a generator axis, the first part connected to the wheel to rotate thereby.

The first part is preferably rotatable with the
15 wheel and the wheel axis and generator axis are coincident. The second part is conveniently attached to a member arranged to be stationery or substantially stationery when the wheel is rotating, preferably by being attached to an offset weight
20 which tends to hold the second part stationery when the wheel rotates. The offset weight conveniently comprises a cross plate attached to the second part and a mass member, preferably a substantially hemi-cylindrical part, the ends of which are connected to
25 the ends of the cross plate so as to be carried by the cross plate eccentrically of the generator axis.

The second part preferably comprises a permanent magnet located within an electro-magnetic core which comprises the first part there being windings on the core connected to the signal emitter to provide it
5 with electric power. The permanent magnet is preferably arranged within north south axis parallel to the generator axis.

Brief Description of the Drawings

Embodiments of the invention will now be described by way of example with reference to the
10 accompanying drawings.

In the drawings:-

Figure 1 is a perspective view of a unit of the invention,

Figure 2 is a longitudinal section through the unit
15 of Figure 1,

Figure 3 is a detail perspective view of the unit partially broken away,

Figure 4 is a section on line 4 - 4 of Figure 2,

Figure 5 is an exploded view of the unit

Figure 6 is a perspective view of the unit in position on a two wheel hub of a lorry
20

Figure 7 is a view in the direction of arrow 7 of Figure 6,

Figure 8 is a diagrammatic view showing the unit of
25 the invention in contact with the receiver,

Figures 9A and 9B are respectively plan and perspective views of a printed circuit board forming part of the unit, and

Figure 10 is a view of a control arrangement of the invention.

Figures 11a-11e show electric circuit diagrams for the main control, a transmitter, the receiver, a pressure sensor and the temperature sensor section of the transmitter.

Referring now to Figures 1 to 8 there is shown a

deflation detector unit 10 of the invention. The unit 10 is intended for use on a hub 12 of a lorry or truck 14. The hub 12 carries two wheels 16 (see Figure 6) respectively carrying tyres 18 (which may be tubeless tyres or tyres with tubes) and includes a shaft end housing 20 on which the unit 10 is carried. A connection 22 is made to the valve of each tyre depressing the core of the valve to hold it open.

This connection 22 includes a flexible hollow pipe 24 which passes through the ventilation openings 26 of the wheels 16 (see Figure 7) and are respectively connected to two "T"-piece 28 which are connected to the unit 10 as will be described below.

The detector unit comprises a cylindrical body 30 the inner end of which fits into the cylindrical rim 32 of a connector/closure plate 34 that is screwed to the shaft end housing 20 and to a pair of plates 36 that are arranged in a cross and two have clamps 38 at their ends holding the "T"-pieces 28 in position. The outer end of the body 30 is closed by a end closure 40 which carries a printed circuit

board (PCB) 42 on its inner face (see Figures 9A and 9B).

5 The body 30 carries the stator 44 of an electric
motor 46 in a recess in a built up central por-
tion 48. The stator 44 comprises an electromagnet
having two arms 50 joined by a cross-member 52. The
rotor of the motor 46 is comprised by a plastic
shaft 54 that is journaled in a carrier disc 56
secured to the end of the portion 48. The shaft has
10 a longitudinal slot in its end and there carries a
permanent magnet 58 projecting beyond the sides of
the slot and having one pole at the end of the shaft
and the other pole at the inward portion of the slot.
The shaft 54 projects through the carrier disc 56 and
15 is there connected to an eccentric weight 60. This
weight 60 comprises a cross-plate 62 secured to its
ends to a heavy part cylindrical mass 64 that sub-
tends slightly more than 180° at the centre. This
mass 64 projects into the annular space 66 between
20 the central portion 48 and the outside wall of the
body 30 and there can be relative rotation between
the body and the weight 60. Thus as the body rotates
with the wheels, the eccentric weight 60 tends to
remain stationary and thus there is relative rotation
25 between the rotor shaft 54 and the stator 44 so that
the motor generates electricity for use as will be
described. There will be two electric pulses per
revolution of the wheel.

The PCB 42 carries a pair of pressure trans-
ducers 68, a transmitter (indicated generally at 70)
and a vibration detector in the form of a hammer 72
carried on a flexible plate 74 that is mounted on the
5 PCB 42.

An electronic temperature sensor is secured to
one of the bolts holding bearing dust cap (not
shown).

The vibration detector serves to detect separ-
10 ation of the tread surface of a tyre from the casing.

The temperature sensor is provided to detect any
undue increase in temperature caused by either a
binding brake or a faulty wheel bearing.

The transducers 68, the vibration detector 72
15 and the temperature sensor are connected to the
transmitter 70 in known manner. A delay mechanism
is incorporated in the electronics of the vibration
detector or of the transmitter to prevent unnecessary
readings from undulations and bumps in the road
20 surface.

The IC chip of the transmitter 70 incorporates a
"sleep timer" which will boot up the transmitter
after a predetermined period, preferably every two
minutes. It will further incorporate a timer that
25 will cause the transmitter to transmit a signal,

which will be highly compressed, after a predetermined period after boot up. This period will differ from wheel to wheel so that the chance of the signal from one transmitter interfering with the signal of another will be minimised if not wholly eliminated. Conveniently the period may be twenty seconds from the end of boot up plus one second for each tyre number, i.e. the transmitter controlled by tyre number 17 will be transmit its signal after thirty seven seconds, i.e. twenty seconds plus seventeen. As each transmitter is controlled by two wheels, it will send out two signals (normally one second apart as the two wheels will normally have consecutive numbers).

15 The chip will receive information from the pressure transducers, vibration detector and temperature sensor at all times. This information will be transmitted by the transmitter, together with a code identifying the wheel in respect of which the signal is being sent during the transmission discussed above.

The antenna for the transmitter 70 is formed by a strip of printed material 71 running around the circumference of the PCB 42.

25 As mentioned above the pipe 22 is connected to the "T"-piece 28, being attached to one arm 76 there-

of, the aligned arm 78 of which is connected to
another pipe 80 which passes through the wall of the
body of the unit and is connected to one of the
transducers 68. The leg 82 of the "T"-piece is
5 connected to a valve body 84 which includes a
Schrader valve and through which the tyre to which it
is connected may be inflated.

The central portion 48 of the body also has a
pair of cylindrical bores 85 within each of which is
10 received a stack of nickel cadmium batteries 86 that
powers the PCB 42 when the vehicle is stationary.
These stacks are connected to be recharged by the
electric motor 46 during travel of the vehicle.

The transmitter 70 on each wheel hub sends
15 signals to a receiver 88 (see Figure 8) that is
located within the cabin 90 of the lorry 14. The
signals identify the tyre about which the signal is
being sent. This receiver has a digital display 92
which gives a reading for the condition of a tyre and
20 a secondary display 94 which identifies the particu-
lar tyre whose condition is being given by the dis-
play 92. In addition there is an audible warning
indicator 96 which is conveniently a buzzer.

The receiver will incorporate a real time clock
25 installed into its electronics and all faults are
stored with the exact time and date attached to them.

It will be appreciated that the receiver will receive information on four separate faults for each axle position, i.e. two pressure signals (one for each tyre), one temperature and one vibration.

5 The receiver will also include a filter which can be "set" before each journey of the lorry 14 so that signals relating only to the particular tyres on the lorry are stored in memory and reflected on the display 92. This "setting" is a "learning" exercise.

10 This exercise occurs when the vehicle is started and continues for the first twenty minutes (which would normally include the ten minutes or so before it commences on a journey during which the engine is allows to warm up). A number of signals may during

15 this time be received as the vehicle may be in a yard in close proximity to other vehicles. The filter then goes into a "verify" cycle for a further twenty minutes during which time it stores the signals received during the first phase, During the third

20 cycle, the receiver clears the register, compares the signals received during the first two phases and then locks on to only those signals that appeared during both phases. Any other signals sent before and after the verify (second) cycles are either

25 ignored or are retained as "rogue" signals. Thus extraneous signals from other lorries which may be travelling with or in the opposite direction to the

lorry 14 will thereafter not affect the signals given by the receiver in that lorry.

Three press buttons 98.1, 98.2 and 98.3 enable the driver to shuttle back and forth to select the particular tyre being checked and also which characteristic is being reported. In addition the receiver contains a computer chip including a counter and a memory that can be down-loaded into a main control computer at vehicle storage garage. One of these buttons is a "re-set" button. When it is depressed, the tyre pressure value at which the warning operation commences is increased, preferably 0,5 Bar up to a maximum, conveniently of 9,5 Bar, whereafter it reverts back to a default setting which is conveniently 5,5 Bar. Another button 98.2 serves to activate the circuit to display the current value of the setting.

The arrangement will operate as follows:- Once the pressure in a tyre falls below a pre-set initial pressure by a unit of pressure, say one half bar, the audible warning indicator 96 will give a warning sound. At the same time the display 94 identifies the tyre and the display 92 indicates the pressure in the tyre. This operation is repeated for each fall of a unit of pressure. If the pressure in more than one tyre falls as aforesaid, the receiver will jump

from the indication of one tyre to the other at the fall of a unit of pressure.

5 The driver of the lorry 14 will now be alerted
if any tyre is deflated. He will know by the time
interval between the unit falls of the tyre (i.e. the
rate at which he receives a signal for each tyre) and
also the degree of deflation indicated whether he
must stop immediately to replace the deflated tyre or
10 whether he can continue to the next place where the
tyre can be inflated and how if at all he must change
his driving speed etc. In addition the particular
tyre will be identified so that when the lorry has
stopped, the driver will be able immediately to
15 inspect the tyre identified by the system as being
faulty. Indeed the driver will get a check of the
condition of tyres before setting out on a journey so
that he can ensure that the tyres are correctly
inflated at that time.

20 In the same way, the driver will receive sig-
nals informing him as to the vibration and tempera-
ture conditions of each axle position.

25 Fitted to each tyre 18 at a convenient position
e.g. at the bead area of the tyre is a micro-trans-
mitter 98 incorporating a lithium battery (not
shown). The micro-transmitter 98 is arranged when
activated (as will be described below) to transmit

over a short distance a unique code signal for the tyre by which it is carried. A receiver (not shown) (hereinafter called a "code receiver") is provided on the PCB 42.

5

Because of the provision of the micro-transmitter 98 in the tyres, a check can be made on the operation and performance of the tyres. An activator plate 100 is placed at the gate of the garage and
10 activates a magnetic switch. As each tyre passes over the plate 100, the magnetic field activates the micro-processor 98 which emits the code signal that is received both by the code receiver and a receiver 102 at the gate which in turn transmits this information
15 to the main garage computer 104. Thus there will be a track of each tyre as it leaves the garage. The plate 100 will also activate the micro-processor 98 on the return of the lorry to the garage and will also activate the transmitter 70 to transmit to the
20 receiver the number of revolutions that the tyre has made, (i.e. one half of the number of pulses received). Thus the main computer will retain information about how many revolutions the tyre has completed and hence the distance (i.e. milage or
25 kilometrage) completed by the tyre. This enables the truck operator to know when the tyre must be retreaded and indeed when the tyre has completed sufficient number of rotations (and has been retreaded sufficiently often) for its life. These

two factors will be detected also by inspection at the garage so that the operator will know other information regarding the tyres and their performance. Possibly more important the operator will
5 know the cost per kilometre for each tyre.

In addition there will be a control when the lorry returns to the garage as the number of rotations made until then, i.e. the exact kilometerage will be supplied to the main computer. Consequently
10 if the lorry does not follow the set down route, this will be apparent to the operator.

As shown in Figure 11 a modified arrangement will incorporate a passive transponder 110 may be inserted into the material of the tread 112 of a
15 tyre 114 instead of the micro processor 98. This can be used where the plate 100 can provide a sufficient magnetic flux to actuate the transponder even when it is at the top of wheel when passing over the plate 100.

20

In the arrangement above described, the information stored in the receiver can be recovered in a number of ways. The information can be downloaded from the receiver by means of a "lap top" computer
25 brought to the receiver 88 at the end of each journey. Alternatively there can be an automatic downloading of data by means of a radio signal to the

main computer 104 the receiver being activated by a magnetic or radio signal activated by the plate 100 (or any other device) at the entrance to the depot to which the vehicle is returning. Of course the data
5 can be captured visually from the receiver 88 and then transferred to the main computer 104 manually.

It will be seen that in addition to the operational advantages mentioned above, there will always be an electric power supply to the transmitter
10 72 when the vehicle is travelling. Thus battery failure, through exhaustion would not be a problem. Indeed the software is arranged to give an indication if any one of the detectors/transmitters is not operating. Furthermore it will be seen that it will
15 be easy to reach the various parts of the unit for maintenance and replacement. In addition it will be seen that the locations for the attachment of the sockets of the inflator for the tyres will be very convenient and much more convenient than in the
20 conventional tyres especially the inner tyres.

The invention is not limited to the precise constructional details hereinbefore described and illustrated in the drawings. The unit can be used on each hub of a lorry having more or less tyres and
25 indeed can be used with advantage on a conventional motor car. The audible warning signal may be a hooter, siren or whistle.

Should the vehicle incorporate a tachograph the receiver may also be linked thereto. When a fault occurs, a pulse is sent to the tachograph which will provide management with a double point of reference as to the exact time and date of the fault as well as all the other information that the tachograph provides such as speed etc.

The code receiver may be provided on a separate receiver within the unit or the main receiver box within the cab.

Electric circuit diagrams for the main control, a transmitter, the receiver, a pressure sensor and the temperature sensor section of the transmitter are shown in Figures 11A, 11B, 11C, 11D and 11E. The circuits are self explanatory when read with the following description of the operation thereof.

TRANSMITTER

On commencement of movement of the truck, the generator 46 activates the circuit. Upon activation, the battery stack 86 is switched into power the circuit. This occurs until the generator voltage exceeds 5 volts. A regulator prevents the voltage increasing further. At this point, the generator 46 supplies full power to the circuit in addition to recharging the battery stack 86. The battery stack 86 is thereafter only used during transmission, when the programmable integrated circuit (PIC) of controller 136 is actuated by the sleep timer mentioned above to transmit signals. The voltage supplied by the generator 46 is rectified by a rectifier bridge 122. At the moment the generator delivers power, a P channel field effect transistor (FET) 123 is switched on connecting battery stack 86 to the circuit. At the same time, an N channel FET 124 completes the circuit. When generator voltage exceeds 4.6 volts BROWN OUT circuit 125 activates switching off P channel FET 123,

this removes the battery from the circuit, placing the battery stack in recharge mode. The battery is only used again during transmission.

5 The tyre pressure is sensed by the pressure transducer 68 (see Figures 9 and 11d). This information is transmitted to the A to D (analogue to digital) converters 126 where it is further processed and stored. The temperature is read via sensor 120 (see Figure 11e) and is also transmitted to the A to D converters 126. Vibration is sensed at sensor 74 and transmitted to the processor's (136) port.

15 The processor 136 stores the above information and puts itself into a unique timing sequence. This timing sequence has been calculated in order to assure transmission without duplication or interference as has been described above. At the end of the timing sequence time out of timing sequence the stored information is transferred to the frequency locked transmitter 70.

RECEIVER

25 The data from each transmitter is recovered by the receiver 88 (see Figure 11c) and transmitted to the programmable integrated circuit (PIC) or processor 129 for the receiver.

The data is stored within the processor 129. If a fault condition occurs, the processor reads the real time clock 130 and at that point it allocates the time and date at which the fault occurred. The fault plus the time and date is then stored on external EE PROM 131. This is to ensure that during power down the fault data is not lost. This fault data can be uploaded via RS 232, 132, to a PC as us described above.

10

The data that is stored in the processor 129 is transferred to the visual display 92, 94 (see Figures 8 and 11a). Dual display 94 displays the tyre number. Dual display 92 displays the value of either pressure or temperature which value is selected by mode switch 98.1. and indicated via LED's 134.1 and 134.2. A vibration fault is indicated at LED 134.3. The specific wheel orientation of the truck (i.e. the side of the vehicle to which the wheel is attached is indicated by LEDS 133.1 (right) and 133.2 (left). The various tyre numbers with their relevant information is down-loaded to the display via the tyre numbers switch 98.3. The mode switch 98.1 sorts out the relevant information. This information is displayed for one minute at which time the display clears.

25

Reset switch 98.2 is used to reset the alarm buzzer 96 and also to set up the desired pressure level at which the alarm will be activated.

- 5 It will be understood that the battery stack can be omitted but in practice it is used because it serves to provide a smooth voltage to the circuit and also to operate the circuit even when the wheels are rotating very slowly.

SECRET

I Claim

1 A tyre condition indicating device comprising a detector for detecting the condition of a tyre on a wheel or a wheel of a vehicle rotatable about a wheel axis, a signal emitter emitting a signal when the detector detects the said condition and power supply means providing power to the signal emitter to emit the signal as aforesaid, wherein the power supply means comprises an electric power generator comprising first and second parts that are relatively rotatable about a generator axis, the first part connected to the wheel to rotate thereby.

4/2 The device as claimed in claim 1^{b3} wherein the first part is rotatable with the wheel and wherein the wheel axis and generator axis are coincident.

3. The device as claimed in claim 1 wherein the second part is attached to a member arranged to be stationery or substantially stationery when the wheel is rotating.

4 A device as claimed in claim 3 wherein the second part is rotatably carried by the wheel and is attached to an offset weight which tends to hold the second part stationery when the wheel rotates.

Sub
a17

5 A device as claimed in claim 4 wherein the offset weight comprises a cross plate attached to the second part and a mass member, the cross plate being rotatable about its centre, through which the generator axis passes, and the mass member being carried by the cross plate eccentrically of the generator axis.

3
6 A device as claimed in claim 5 wherein the mass member comprises a substantially hemi-cylindrical part, the ends of which are connected to the ends of the cross member.

8
7 A device as claimed in claim 6 wherein the second part comprises a permanent magnet located within an electro-magnetic core which comprises the first part there being windings on the core connected to the signal emitter to provide it with electric power.

9
8 A device as claimed in claim 7 wherein the permanent magnet is arranged with its north/south axis parallel to the generator axis.

a 3
4 A device as claimed in claim 8 incorporating a housing with a generally cylindrical inner part centred on the generator axis and having an opening therein within which the core is received and a rotary support carrying the second part, there being

an annular space between the housing and the inner part within which space the hemi-cylindrical part is movable about the generator axis.

¹⁵
~~10~~ A device as claimed in claim ~~4~~¹³ preceding ~~claims~~ wherein the detector is a tyre pressure detector.

¹⁸
~~11~~ A device as claimed in claim ~~10~~¹⁵ for use with a tyre incorporating a tube that has a valve projecting through the wheel wherein the tyre pressure detector comprises a pressure transducer and a conduit connecting the transducer to the valve.

¹⁶
~~12~~ A device as claimed in claim ~~10~~¹⁵ for use with a tubeless tyre having a valve projecting from the wheel, and wherein the entire pressure detecting incorporates a pressure transducer connected to the valve by a conduit.

¹⁹
~~13~~ A device as claimed in claim ~~11~~¹⁸ further comprising a union connected in the conduit and incorporating a valve control member inlet through which the tyre can be inflated via the conduit.

¹⁷
~~14~~ A device as claimed in claim ~~12~~¹⁶ further comprising a union connected in the conduit and incorporating a valve control member inlet through which the tyre can be inflated via the conduit.

a
~~15~~¹⁰ A device as claimed in claim ~~1~~³ wherein the the signal emitter comprises a radio frequency transmitter carried by a printed circuit board.

~~16~~¹¹ A device as claimed in claim ~~15~~¹⁰ wherein the transmitter has an antenna formed from the printed circuit board.

~~20~~²⁰ A device as claimed in claim ~~11~~¹⁸ wherein the the signal emitter comprises a radio frequency transmitter carried by a printed circuit board and wherein the transducer is mounted on the printed circuit board.

*100%
2007*
18 A device as claimed in claim 1 further comprising a counter connected to the transmitter whereby the transmitter can transmit a signal equivalent to the number of rotations that each wheel makes during a particular journey.

~~19~~² A device as claimed in claim ~~18~~¹ wherein the counter counts the number of relative revolutions of the first and second parts of the electric generator.

a
~~20~~⁵ A double wheel arrangement comprising a pair of wheels respectively carrying a pair of tires and a tyre indicating device as claimed in claim ~~1~~³ comprising a pair of detectors coupled respectively to the tires.

¹²
~~21~~ A vehicle comprising a plurality of wheels each carrying a tyre and tyre condition indicating devices as claimed in claim ~~21~~¹³

¹³
~~22~~ A vehicle as claimed in claim ~~21~~¹² further comprising a driver's cabin and, within the driver's cabin, a receiver for receiving signals from the transmitter.

¹⁴
~~23~~ A vehicle as claimed in claim ~~22~~¹³ wherein the receiver incorporates indicating means identifying each tyre whereby the driver will receive signals indicating the condition of each tyre.

The schematic diagram shows a PIC microcontroller at its core. On the left, there are input sections labeled 98.1 (RECEIVE/FUNCTION), 98.2 (VIBCO), and 98.3 (TYPE NUMBER), each with associated resistors and logic gates. A BATTERY provides power to the system. The PIC's output pins are connected to several components: a printer (PRINTER) via a relay (92); two sets of LEDs (133-1, 133-2 and 134-1, 134-2) through current-limiting resistors (129); and another relay (94). A buzzer (96) is also connected to the PIC's output. Various other components like capacitors and diodes are shown throughout the circuit.

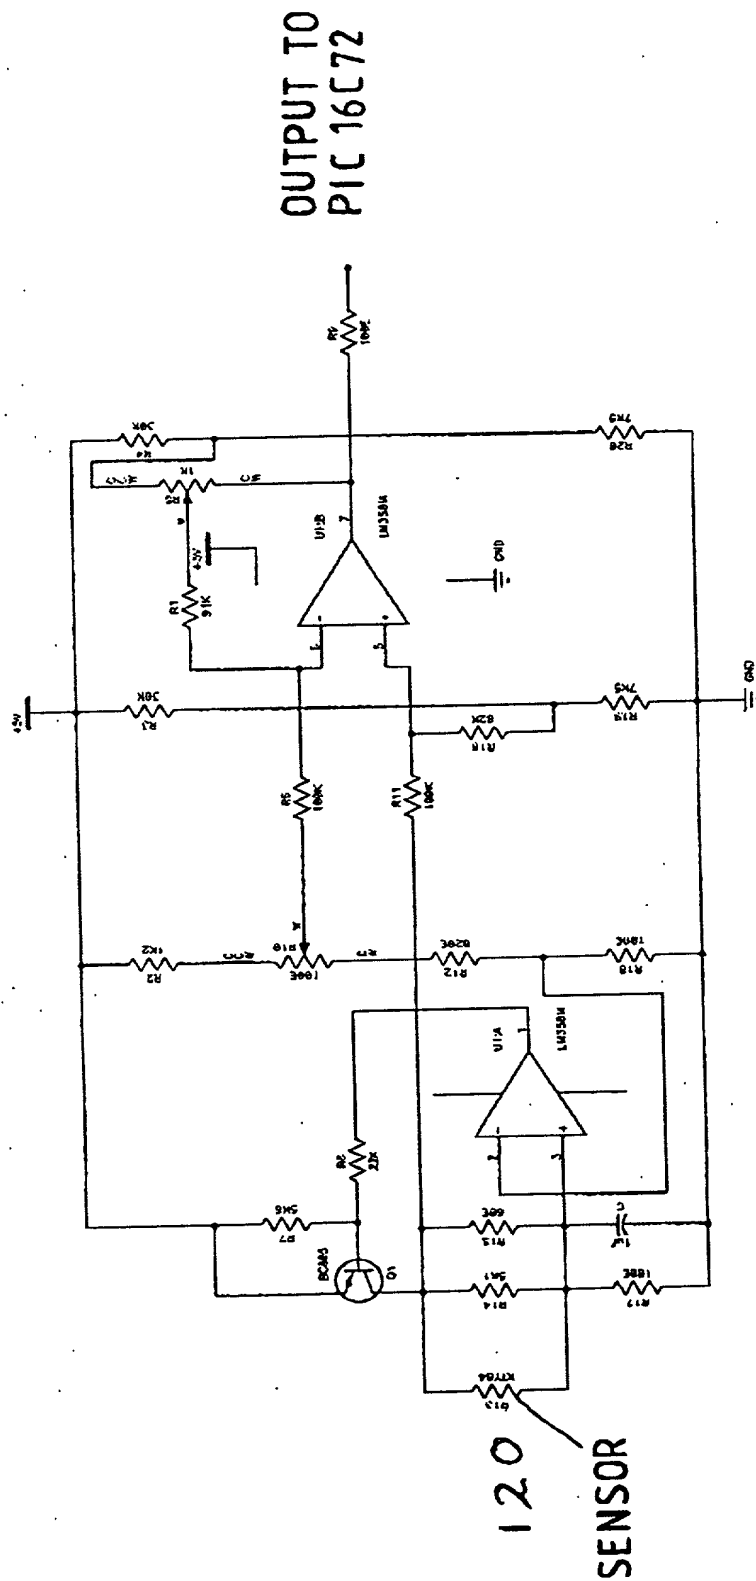

FIG. 11e

DECLARATION AND POWER OF ATTORNEY FOR PATENT APPLICATION

Attorney Docket No. 9007-2

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name.

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled _____

TYRE DEFLATION DETECTOR

the specification of which

☒ is attached hereto

OR

☐ was filed on _____ as United States Application No. or PCT International Application Number _____ and was amended on _____ (if applicable).

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to patentability as defined in Title 37 Code of Federal Regulations, § 1.56.

I hereby claim foreign priority benefits under Title 35, United States Code, § 119(a)-(d) or § 365(b) of any foreign application(s) for patent or inventor's certificate, or § 365(a) of any PCT International application which designated at least one country other than the United States of America, listed below and have also identified below any foreign application for patent or inventor's certificate, or of any PCT International application having a filing date before that of the application on which priority is claimed.

Attorney's Docket No. 9007-2

Applicant or Patentee: KEVIN PATRICK AUSTIN PEARMAN

Serial No. or Patent No.: _____

Filed or Issued: _____

Title: TYRE DEFLATION DETECTOR

VERIFIED STATEMENT (DECLARATION) CLAIMING SMALL ENTITY STATUS
(37 C.F.R. § 1.9(f) and 1.27(b)) - INDEPENDENT INVENTOR

As a below named inventor, I hereby declare that I qualify as an independent inventor as defined in 37 C.F.R. § 1.9(c) for purposes of paying reduced fees under section 41(a) and (b) of Title 35, United States Code, to the Patent and Trademark Office described in:

☒ the specification filed herewith.

☐ the application identified above.

☐ the patent identified above.

I have not assigned, granted, conveyed, or licensed and am under no obligation under contract or law to assign, grant, convey, or license any rights in the invention to any person who could not be classified as an independent inventor under 37 C.F.R. § 1.9(c) if that person had made the invention, or to any concern which would not qualify as a small business concern under 37 C.F.R. § 1.9(d) or nonprofit organization under 37 C.F.R. § 1.9(e).

Each person, concern, or organization to which I have assigned, granted, conveyed, or licensed or am under an obligation under contract or law to assign, grant, convey, or license any rights in the invention is listed below:

☒ No such person, concern, or organization exists.

☐ Each such person, concern, or organization is listed below.*

FULL NAME: _____

ADDRESS: _____

☐ INDIVIDUAL ☐ SMALL BUSINESS ☐ NONPROFIT ORGANIZATION

FULL NAME: _____

ADDRESS: _____

☐ INDIVIDUAL ☐ SMALL BUSINESS ☐ NONPROFIT ORGANIZATION

*NOTE: Separate verified statements are required from each named person, concern, or organization having rights to the invention averring to their status as small entities. (37 C.F.R. § 1.27)

I acknowledge the duty to file, in this application or patent, notification of any change in status resulting in loss of entitlement to small entity status prior to paying, or at the time of paying, the earliest of the issue fee or any maintenance fee due after the date on which status as a small entity is no longer appropriate. (37 C.F.R. § 1.28(b))

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application, any patent issuing thereon, or any patent to which this verified statement is directed.
